

# On testing problems in linear models with two variance-covariance components

Julia Volaufova

Louisiana State University Health Sciences Center,  
New Orleans, USA

Linear models with variance-covariance components are used in a wide variety of applications. A special case of models with two variance-covariance components have been studied extensively for decades. Most often the objective of inference is testing linear hypotheses about the mean of the response. Even assuming multivariate normality, it is not clear what test to recommend except in a few special settings, such as balanced or orthogonal designs. Here we shall investigate a simultaneous hypothesis on the mean and on the between-subject variance component (see Crainiceanu & Ruppert, 2004) and in that setting special cases of hypotheses will be studied. We shall show some statistical properties of test procedures, such as accuracy of  $p$ -values and powers of approximate and exact tests.
