January 14, 2005

# 1. Latent Class (LC) and Finite Mixture (FM) Models

- General definition: parameters of the model of interest differ across unobserved subgroups
- Most important applications:
  - (probabilistic) clustering
  - scaling / measurement error / discretized IRT
  - density estimation
  - unobserved heterogeneity / correlated observations / (nonparametric) random-effects modeling
- Latent GOLD implements these applications in three modules: LC cluster, LC factor, and LC regression
  - not as flexible as possible, but flexible enough
  - as easy (interface, graphs, output measures), save (random starts / Bayes constants, diagnostics), fast, and stable (EM +NR) as possible
  - work in progress: restrictions / choice / longitudinal / multilevel / complex sampling
- Traditional LC model (Lazarsfeld & Goodman)
  - LC cluster model with nominal observed variables
  - independence model with different parameters for each latent class (=local independence)

## 2. General Latent GOLD Model

- Simple probability structure from which the three modules are derived

$$P(Y | Z) = \sum_x P(X | Z)P(Y | X, Z)$$

- $Y$  is a set of dependent/response/endogenous variables
  - $Z$  is a set of independent/predictor/exogenous variables
  - $X$  is a set of nominal/ordinal latent variables
  
  - density  $P(Y|Z)$  is a weighted average of class-specific densities, which are from the exponential family (multinomial, Poisson, normal)
  - in most cases: local independence between replications
  - MIMIC model
- For example, the traditional latent class model is:

$$P(y_1 y_2 y_3) = \sum_{x_1} P(x_1)P(y_1 | x_1)P(y_2 | x_1)P(y_3 | x_1)$$

- note: all  $Y$ 's are nominal, no  $Z$ 's, a single  $X$
- A GLM is specified for each  $Y$  variable
  - with nominal/ordinal variables these are logit models:

$$P(y_1 | x_1) = \frac{\exp(\alpha_{y_1} + \beta_{y_1 x_1})}{\sum_{y_1} \exp(\alpha_{y_1} + \beta_{y_1 x_1})}$$

### 3. The Traditional LC Model

- EXAMPLE General Social Survey 1982, white sample (see McCutcheon, 1987; Magidson & Vermunt, Soc. Meth. 2001)
  - evaluation of surveys by respondent (2 questions)
  - evaluation of respondent by interviewer (2 questions)
  - are there different types of survey respondents?

| PURPOSE | ACCURACY    | UNDERSTANDING | COOPERATION       | Whites | Blacks |
|---------|-------------|---------------|-------------------|--------|--------|
| Good    | Mostly true | Good          | Interested        | 419    | 117    |
|         |             |               | Cooperative       | 35     | 14     |
|         |             |               | Impatient/Hostile | 2      | 3      |

## 4. Model Selection, Classification, Estimation, and Problems

### 4.1 Model selection

- Chi-squared statistics
  - overall tests: L-squared and X-squared
  - conditional tests: regularity conditions
  - sparseness
- Analysis of association
  - proportional reduction of L-squared
- Information criteria: BIC, AIC, CAIC
  - model comparison
  - parsimony versus fit
- Bivariate residuals
  - local lack of fit
- Quality of classification
  - see classification
  - fit, parsimony, and classification: AWE

## 4.2 Classification

- After estimating a LC model, we can classify individuals into latent classes
- Latent classification or posterior membership probabilities

$$P(x_1 | y_1 y_2 y_3) = \frac{P(x_1)P(y_1 | x_1)P(y_2 | x_1)P(y_3 | x_1)}{\sum_{x_1} P(x_1)P(y_1 | x_1)P(y_2 | x_1)P(y_3 | x_1)}$$

- Allocation methods
  - modal allocation
  - proportional allocation
  - random allocation (+ multiple)
- Quality of classification
  - proportion of classification errors
  - reduction of classification errors
  - other reduction of errors measures

EXAMPLE GSS'82 data (continued)

*Classification output for 3-cluster model*

---

## 4.3 Estimation

- Maximum likelihood (ML)
  - standard estimation method in LC analysis
  - known favorable properties like unbiasedness, consistency, etc.
  - probability density for data: multinomial distribution (not restrictive at all)
  - easy to adapt to other types of  $Y$  variables (see mixture models and LC cluster)

- Kernel log-likelihood function:

$$\begin{aligned}\ln Lik &= \sum_{y_1 y_2 y_3} n_{y_1 y_2 y_3} \ln P(y_1 y_2 y_3) \\ &= \sum_{y_1 y_2 y_3} n_{y_1 y_2 y_3} \ln \sum_{x_1} P(x_1) P(y_1 | x_1) P(y_2 | x_1) P(y_3 | x_1)\end{aligned}$$

- EM algorithm
  - general iterative method for ML estimation with missing data (here  $X_1$  is missing)
  - E step: fill in missing data
  - M step: estimate parameters in the usual way
  - stable (converges irrespective of starting values)
  - fast per iteration, but may need many iterations

- E step

$$\hat{n}_{x_1 y_1 y_2 y_3} = n_{y_1 y_2 y_3} P(x_1 | y_1 y_2 y_3)$$

$$P(x_1 | y_1 y_2 y_3) = \frac{P(x_1)P(y_1 | x_1)P(y_2 | x_1)P(y_3 | x_1)}{\sum_{x_1} P(x_1)P(y_1 | x_1)P(y_2 | x_1)P(y_3 | x_1)}$$

- M step

$$\ln Lik^* = \sum_{x_1 y_1 y_2 y_3} \hat{n}_{x_1 y_1 y_2 y_3} \ln P(x_1)P(y_1 | x_1)P(y_2 | x_1)P(y_3 | x_1)$$

$$P(x_1) = \hat{n}_{x_1} / N, \quad P(y_1 | x_1) = \hat{n}_{x_1 y_1} / \hat{n}_{x_1}, \text{ etc..}$$

- M step becomes a bit more complicated when a conditional density is restricted by a GLM. But, standard complete data methods can be used.

- Newton-Raphson algorithm
  - standard optimization algorithm
  - first and second derivatives log-likelihood
  - unstable (needs good starting values)
  - fast when near to the maximum
  
- Latent Gold: hybrid algorithm
  - EM when far from the maximum
  - Newton-Raphson when close enough to maximum

## 4.4 Problems and possible solutions

- Non-identification
  - different sets of parameter estimates yield the same value of L-squared: estimates are not unique
  - detection: running the model with different sets of starting values, or formally from the rank of the information matrix
  - famous example: 3-cluster model for 4 dichotomous indicators
- Local maxima
  - there are different sets of 'ML' parameter estimates with different  $L^2$  values
  - we want the solution with lowest  $L^2$  (highest likelihood)
  - solution: multiple sets of starting values
  - example GSS'82: 3-cluster model with  $L^2$  of 37.57 instead of 22.09
- Boundary solutions
  - estimated probability becomes zero, or log-linear parameters extremely large negative
  - solution: using priors to smooth the estimates
  - example GSS'82: 3-cluster model contains 2 zero probabilities

## 5. Extensions of the Traditional LC Model

- 4 most important extensions of traditional LC model
  - several latent variables (LC factor)
  - local dependencies
  - ordinal variables
  - covariates

### 5.1 Several latent variables (LC factor model)

- When items don't measure a single dimension, we may introduce a second latent variable
  - Similar to (confirmatory/exploratory) factor analysis
- For example, two latent variables:

$$P(y_1 y_2 y_3) = \sum_{x_1 x_2} P(x_1 x_2) P(y_1 | x_1 x_2) P(y_2 | x_1 x_2) P(y_3 | x_1 x_2)$$

$$\text{with: } P(y_1 | x_1 x_2) = \frac{\exp(\alpha_{y_1} + \beta_{y_1 x_1} + \beta_{y_1 x_2})}{\sum_{y_1} \exp(\alpha_{y_1} + \beta_{y_1 x_1} + \beta_{y_1 x_2})}$$

some  $\beta$ 's may be set equal to zero

- This is done in the LC factor module, with the additional restriction that the latent variables are dichotomous/ordinal (see Magidson and Vermunt, Soc. Meth. 2001).

## 5.2 Local dependencies

- Why doesn't a LC model fit?
  - because local independence assumption is violated
- 3 possible solutions:
  1. increase the number of clusters or latent classes
  2. increase the number of factors or latent variables
  3. allow for local dependencies or direct relationships between certain items
- Option 3 is similar to correlated errors in structural equation models
- For example:

$$P(y_1 y_2 y_3) = \sum_x P(x_1) P(y_1 y_2 | x_1) P(y_3 | x_1)$$

with:

$$P(y_1 y_2 | x_1) = \frac{\exp(\alpha_{y_1} + \alpha_{y_2} + \alpha_{y_1 y_2} + \beta_{y_1 x_1} + \beta_{y_2 x_1})}{\sum_{y_1 y_2} \exp(\alpha_{y_1} + \alpha_{y_2} + \alpha_{y_1 y_2} + \beta_{y_1 x_1} + \beta_{y_2 x_1})}$$

- Interpretation: two items are more strongly related than can be explained by clusters/factors
- Exploratory versus theoretical justification
- Detection: bivariate residuals (kind of modification indices)

## EXAMPLE: Political orientation (Hagenaars, 1993)

5 dichotomous variables

- system responsiveness (low/high)
- ideological level (nonideologies/ideologies)
- repression potential (high/low)
- protest approval (low/high)
- conventional participation (low/high)

*Fit measures:*

| Model                       | L-squared | BIC  | df | p-value |
|-----------------------------|-----------|------|----|---------|

| 2-cluster                   | 95.82     | -45  | 20 | 0.00    |
| 3-cluster                   | 24.80     | -74  | 14 | 0.04    |
| 4-cluster                   | 7.45      | -49  | 8  | 0.49    |
| 2-factor                    | 12.30     | -86  | 14 | 0.58    |
| 2-cluster + 1 direct effect | 19.10     | -115 | 19 | 0.45    |

*Bivariate residuals in 2-cluster model*

| Indicators | SYS_RESP | IDEO_LEV | REP_POT        | PROT_APP |
|------------|----------|----------|----------------|----------|
| IDEO_LEV   | 0.6751   |          |                |          |
| REP_POT    | 3.5917   | 0.3085   |                |          |
| PROT_APP   | 0.1405   | 0.0739   | <b>57.8794</b> |          |
| CONV_PAR   | 2.5345   | 0.5543   | 3.2535         | 2.0772   |

## 5.3 Ordinal indicators

- So far: dichotomous or unordered polytomous indicators
- When indicators are ordinal, we can restrict their relationship with the latent variable(s)
- Several options
  1. different types of logits
    - adjacent-category logit
    - cumulative logit (or probit)
    - continuation-ratio logit
  2. inequality restrictions
  3. binomial count (k out of K)
- In Latent Gold, we work with adjacent category logit models with fixed scores for item categories, for example

$$\beta_{y_1 x_1} = \beta_{x_1} y_1$$

- Assumption: local odds-ratios are category independent
- Note: in the LC factor model, we assume that the latent variables are ordinal

EXAMPLE GSS'82 data (continued)

*Fit measures*

| Model   |           | L <sup>2</sup> | BIC     | df | p-value |
|---------|-----------|----------------|---------|----|---------|
| Nominal | 1-Cluster | 257.26         | 51.60   | 29 | 0.00    |
|         | 2-Cluster | 79.51          | -76.51  | 22 | 0.00    |
|         | 3-Cluster | 22.09          | -84.29  | 15 | 0.11    |
| Ordinal | 1-Cluster | 257.26         | 51.60   | 29 | 0.00    |
|         | 2-Cluster | 82.60          | -87.60  | 24 | 0.00    |
|         | 3-Cluster | 30.67          | -104.07 | 19 | 0.04    |

*Profile output ordinal 3-cluster (constraint?)*

|                   | Cluster1 | Cluster2 | Cluster3 |
|-------------------|----------|----------|----------|
| Cluster Size      | 0.6407   | 0.1925   | 0.1668   |
| PURPOSE           |          |          |          |

| fair/poor         | 0.0051   | 0.2517   | 0.7973   |
| COOPERAT          |          |          |          |
| interested        | 0.9362   | 0.6365   | 0.6971   |
| cooperative       | 0.0609   | 0.2754   | 0.2412   |
| impatient/hostile | 0.0029   | 0.0881   | 0.0617   |

## 5.4 Covariates

- Other terms: exogenous, explanatory, external, independent, concomitant, or predictor variables
- Probably most important extension of standard LC model
- Covariates to predict class membership: joint classification and prediction
- More elegant than separate classification and prediction
- Covariates may be nominal or continuous/numeric
- A model with two nominal covariates:

$$P(y_1 y_2 y_3 \mid z_1 z_2) = \sum_{x_1} P(x_1 \mid z_1 z_2) P(y_1 \mid x_1) P(y_2 \mid x_1) P(y_3 \mid x_1)$$

with a logit model for the latent variable:

$$P(x_1 \mid z_1 z_2) = \frac{\exp(\alpha_{x_1} + \beta_{x_1 z_1} + \beta_{x_1 z_2})}{\sum_{x_2} \exp(\alpha_{x_2} + \beta_{x_2 z_1} + \beta_{x_2 z_2})}$$

- Alternative: inactive covariates

EXAMPLE: Political orientation (Hagenaars, 1993)

*Parameters output*

| <i>Latent Variable(s) (gamma)</i> |          |          |          |  |

## 6. Simple Mixture Models

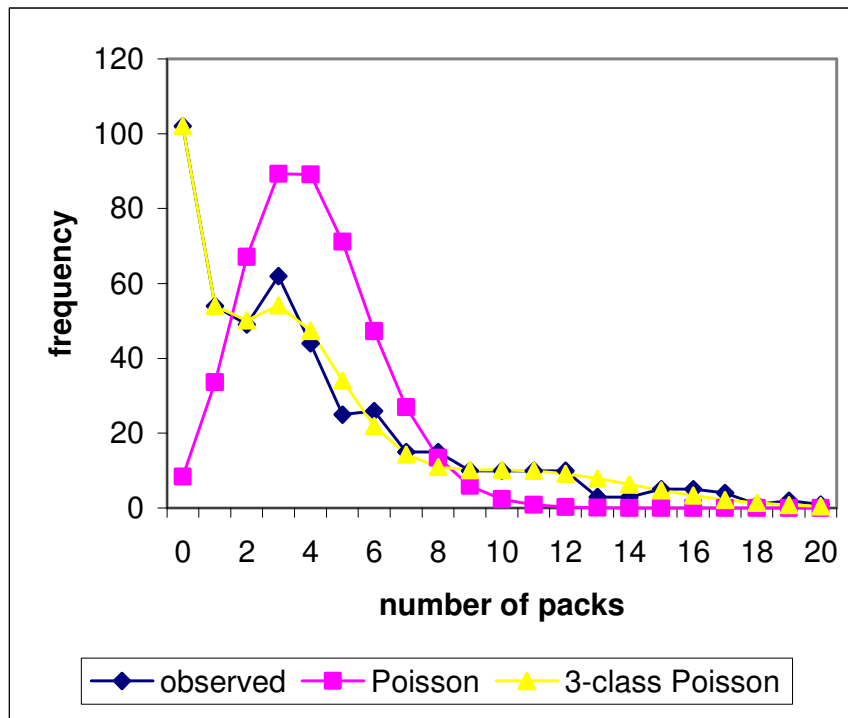

- Basic idea of mixture models
  - unobserved heterogeneity
  - parameters of the specified model are different for subgroups
  - unknown to which subgroup someone belongs
  - subgroups are latent classes
- Applicable to:
  1. univariate distributions: mean + variance
    - density estimation
    - clustering
  2. multivariate distributions: means + variances/covariances
    - multivariate density estimation
    - clustering
  3. regression models: coefficients
    - clustering using a regression model
    - unobserved heterogeneity
    - dependence between observations
  4. more complex models: coefficients
- Note: standard LC model is also a mixture model
- Estimation, testing, and classification issues same as in models discussed so far

## Mixtures of univariate distributions

- A single  $Y$ , which mean and variance differs across subgroups
- In Latent Gold,  $Y$  may be nominal, ordinal, count, or continuous
- Formula:  $P(y_1) = \sum_{x_1} P(x_1)P(y_1 | x_1)$
- The exact form of  $P(y_1 | x_1)$  depends of the type of  $Y$  variable

EXAMPLE: Mixture of Poisson distributions (weekly consumption of hard-candy)

*Observed and estimated distributions*

*Fit measures*

| Model   | LL       | BIC     | Npar |
|---------|----------|---------|------|
| 1-Class | -1545.00 | 3096.12 | 1    |
| 2-Class | -1188.83 | 2396.03 | 3    |
| 3-Class | -1132.04 | 2294.70 | 5    |
| 4-Class | -1130.08 | 2303.01 | 7    |
| 5-Class | -1130.07 | 2315.25 | 9    |

## 7. LC or Model-Based Clustering

- LC analysis is becoming a popular clustering tool
- Is application of mixtures of multivariate distributions
- Clustering via LC or mixture models has many advantages over traditional types of cluster analysis:
  - large samples
  - mixed mode data
  - no linear scale transformation necessary
  - favorable properties of statistical model: model options, statistical tests

- Basic formula:

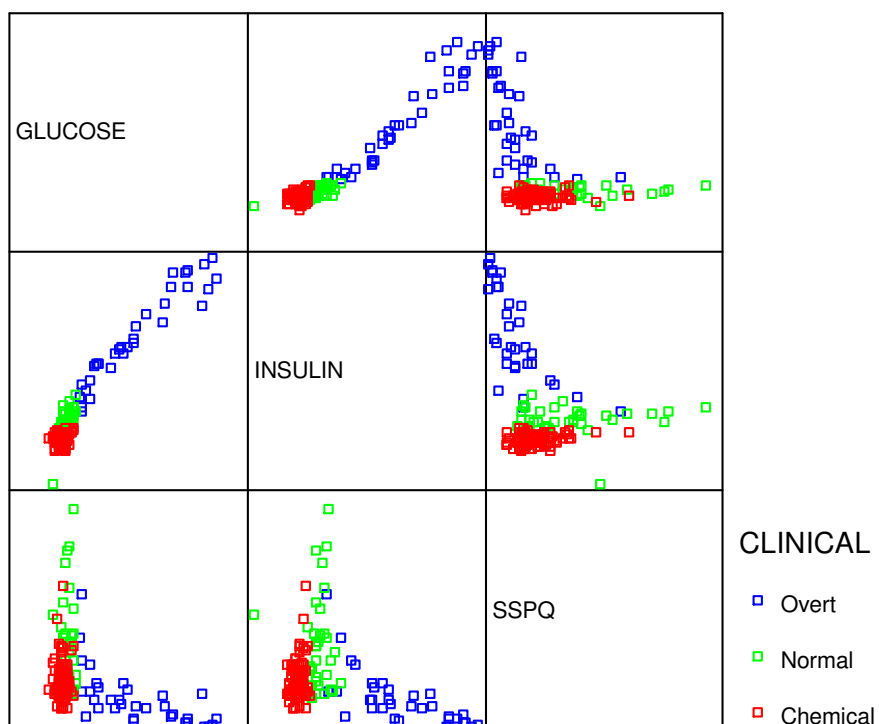

$$P(y_1 y_2 y_3) = \sum_{x_1} P(x_1) P(y_1 | x_1) P(y_2 | x_1) P(y_3 | x_1)$$

- Same basic assumption as standard LC model, which is, in fact, the special case with all variables nominal/ordinal. Local independence assumption can be relaxed.
- Mixed mode data: choosing the appropriate probability density function for each indicator variable
  - nominal: multinomial
  - ordinal: restricted multinomial
  - counts: Poisson / binomial
  - continuous: (multivariate) normal
- LC cluster versus K-means

## EXAMPLE: Diabetes data

Three continuous measures to diagnose diabetes: Glucose, Insulin, and SSPG (steady-state plasma glucose)

Information on the clinical diagnosis: "normal", "chemical diabetes", and "overt diabetes"

Note: cluster forms/shapes are very different from K-means clusters

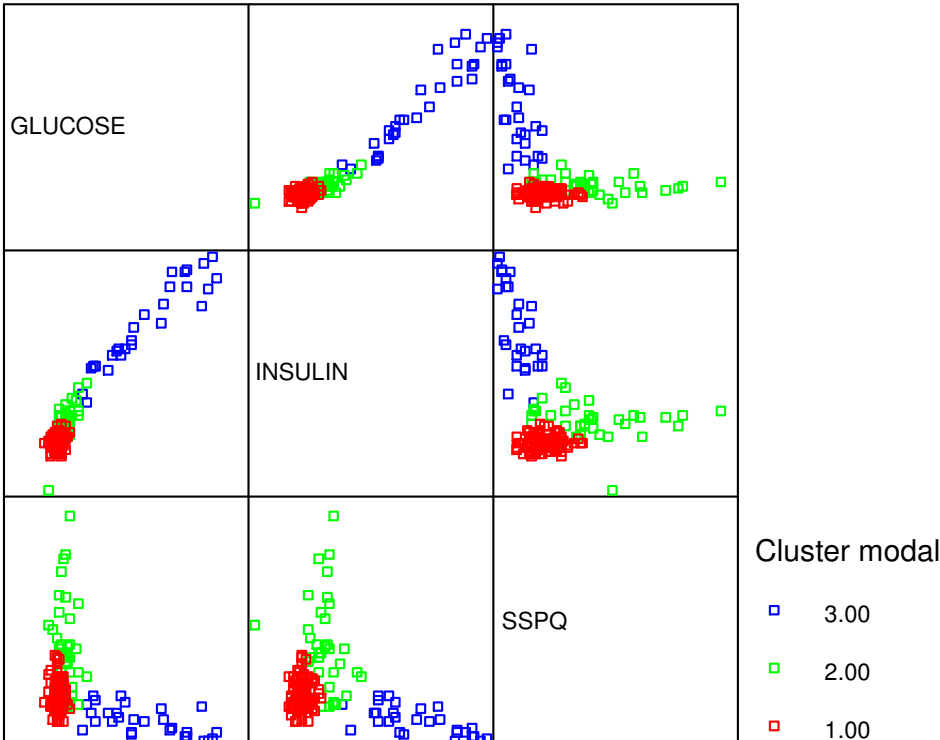

*Fit measures*

| Model                          | LL       | BIC     | Npar |
|--------------------------------|----------|---------|------|
| Equal and diagonal             |          |         |      |
| 1-Cluster                      | -2750.13 | 5530.13 | 6    |
| 2-Cluster                      | -2559.88 | 5169.52 | 10   |
| 3-Cluster                      | -2464.78 | 4999.24 | 14   |
| 4-Cluster                      | -2424.46 | 4938.49 | 18   |
| 5-Cluster                      | -2392.56 | 4894.60 | 22   |
| Unequal and diagonal           |          |         |      |
| 1-Cluster                      | -2750.13 | 5530.13 | 6    |
| 2-Cluster                      | -2446.12 | 4956.94 | 13   |
| 3-Cluster                      | -2366.92 | 4833.38 | 20   |
| 4-Cluster                      | -2335.38 | 4805.13 | 27   |
| 5-Cluster                      | -2323.13 | 4815.47 | 34   |
| Unequal and full               |          |         |      |
| 1-Cluster                      | -2546.83 | 5138.46 | 9    |
| 2-Cluster                      | -2359.12 | 4812.80 | 19   |
| 3-Cluster                      | -2308.64 | 4761.61 | 29   |
| 4-Cluster                      | -2298.59 | 4791.28 | 39   |
| 5-Cluster                      | -2284.97 | 4813.79 | 49   |
| Unequal and $y_1$ - $y_2$ free |          |         |      |
| 1-Cluster                      | -2560.40 | 5155.64 | 7    |
| 2-Cluster                      | -2380.27 | 4835.19 | 15   |
| 3-Cluster                      | -2320.57 | 4755.61 | 23   |
| 4-Cluster                      | -2303.14 | 4760.56 | 31   |
| 5-Cluster                      | -2295.05 | 4784.19 | 39   |

### K-Means type model

### Final 3-cluster model

## EXAMPLE: cancer data (mixed mode)

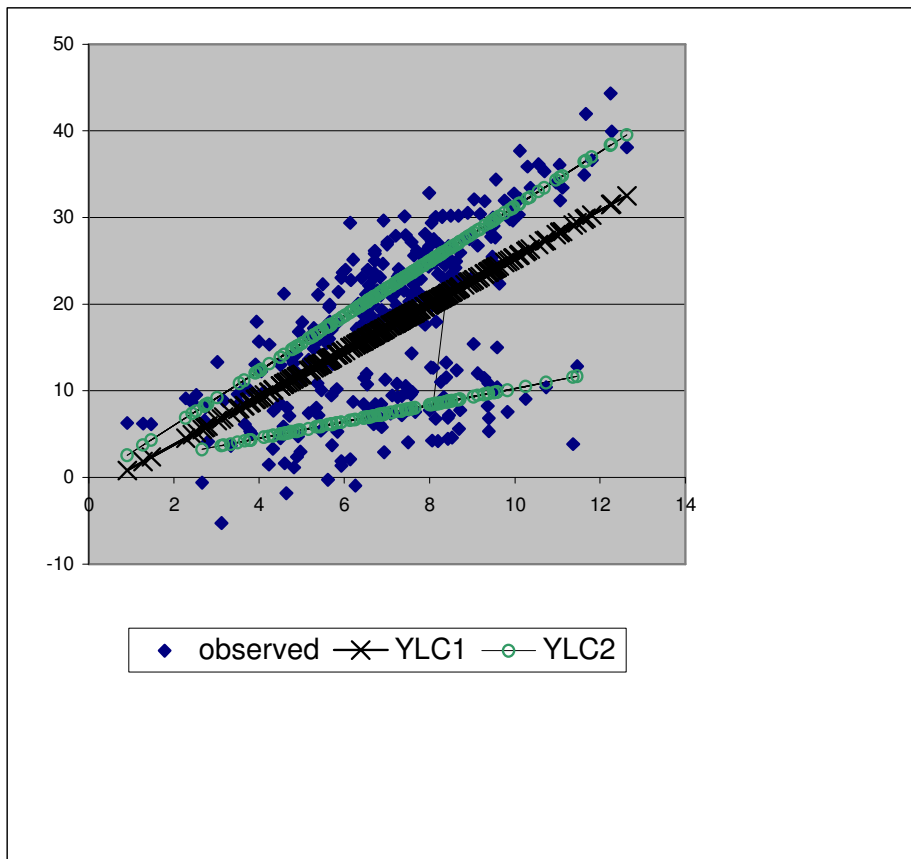

mixed mode data: 8 continuous and 4 nominal variables

class-dependent variances

| Model   | LL     | BIC   | Npar | class. errors |
|---------|--------|-------|------|---------------|
| 1 class | -11798 | 23762 | 27   | 0.000         |
| 2 class | -11386 | 23112 | 55   | 0.036         |
| 3 class | -11289 | 23089 | 83   | 0.100         |
| 4 class | -11202 | 23088 | 111  | 0.111         |

## 8. LC or Mixture Regression Models

- Single  $Y$  and one or more  $Z$ 's
- Formula:  $P(y_1 | Z) = \sum_{x_1} P(x_1)P(y_1 | x_1, Z)$
- The parameters of the model in which  $Y$  is regressed on  $Z$  differ across latent classes

- One way of seeing the model: cluster analysis based on a regression model
- Another perspective: two-level nonlinear mixed model
  - non-parametric specification random-effects
  - replications / repeated measures
  - level-1 predictors and level-2 predictors (covariates)
  - fixed (class-independent) and random (class-dependent) coefficients
  - very fast and stable compared to standard nonlinear mixed models

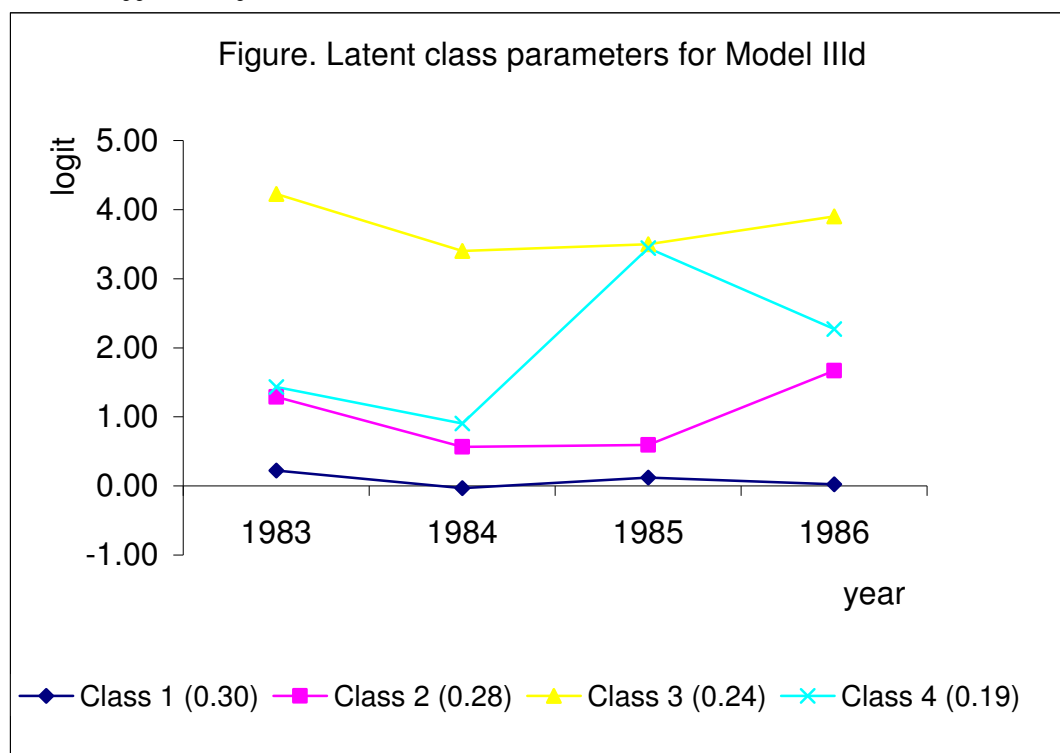

## EXAMPLE: mixture binomial regression for longitudinal data

- Attitude towards abortion measured at 4 time points
- Class-independent predictor religion
- Non-parametric random-coefficient model
- See Vermunt & Van Dijk, 2001, Multilevel Modelling Newsletter

### *Fit measures*

|         | LL       | BIC     | Npar |
|---------|----------|---------|------|
| 1-Class | -2188.38 | 4415.80 | 7    |
| 2-Class | -1745.42 | 3557.75 | 12   |
| 3-Class | -1682.71 | 3460.21 | 17   |
| 4-Class | -1656.72 | 3436.10 | 22   |
| 5-Class | -1645.20 | 3440.96 | 27   |

### *Time effects for 4 latent classes*

## 9. LC Models for Choice Data

EXAMPLE: choice based conjoint experiment

- special case of LC regression
  - conditional logit model
  - choice-specific predictors
- 3 data files: responses, alternatives, choice sets
- responses on 8 choice tasks (3 alternatives + none)
- 400 cases
- effect of product attributes on choice
  - fashion (traditional/modern)
  - quality (low/high)
  - price (2-6)
  - none dummy
- purpose: find market segments for market simulations

## 10. Other Types of LC and FM Models

- Latent class scaling models
- Mixture variants of (regression) models for paired comparison, ranking, and other types of choice data
- Mixture variants of models for dependent/longitudinal data, such as Markov models and Rasch models
- Latent Markov models
- Loglinear models with latent variables
- Mixture variants of structural equation models

## 11. Some References on LC and FM models
